Dedication

This thesis is dedicated to my great parents for their unconditional love, prayers, endless support and encouragement, my dearest wife, who leads me through the valley of darkness with light of hope and support and my beloved brother and sisters.

ACKNOWLEDGMENTS

I am extremely grateful to Allah who gave me the health and ability to accomplish this work. I would like to thank King Fahd University of Petroleum and Minerals (KFUPM) for giving me the opportunity to complete my master's degree.

I would never have been able to finish my thesis without the guidance of my committee members, help from friends, and support from my family and wife. I would like to express my deepest gratitude to my advisor Dr. Khalid Alhooshani for his excellent guidance, caring, patience, and providing me with an excellent atmosphere for doing research and directions as well as the other committee members: Dr. Abdulaziz Alsaadi and Dr. Tawfik A. Saleh. My special thanks to the chemistry department presented by Dr. Abdullah J. Al-Hamdan and my graduate advisor Dr. Bassam Al-Ali for their assistance and help during my studies. And all of my thanks to the chemistry department faculty and staff.

ABSTRACT (ENGLISH)

Full Name : Mohammed Salah Ahmed Abdelbassit
Thesis Title : Adsorption of chloromethanes from water using activated carbon /
metal oxides nanoparticles
Major Field : Chemistry
Date of Degree : May, 2014

In the presented work, four adsorbents: activated carbon derived from waste tire rubber, activated carbon loaded with zinc oxide nanoparticles (ZnO/AC), silica nanoparticles and Ceria nanoparticles were prepared and examined for removal of chloromethanes namely: dichloromethane, trichloromethane and carbon tetrachloride from aqueous solutions. Nanoporous carbon (NC) prepared from waste tires by pyrolysis. Further surface-modification was carried out by successive treatment with H_2O_2 and HNO_3 and the composites were prepared by co-precipitation methods followed by calcinations at high temperature. The produced adsorbents were characterized using different techniques such as scanning electron spectroscopy (SEM), energy dispersive X-ray spectroscopy (EDX), FTIR spectrophotometer, and X-ray diffraction. Batch experiments were performed by using different adsorbent dosages, initial concentrations, and contact time. The kinetics of the adsorption for these pollutants onto the adsorbents was undergone to the pseudo second-order kinetic model, Freundlich and Langmuir models were applied to the adsorption process and the hydrophilic fraction adsorption fitted the intraparticle diffusion model. The order of the sorption efficiency is as following: $\text{SiO}_2\text{-NP/AC} > \text{ZnO-NP/AC} > \text{CeO}_2\text{-NP/AC} > \text{AC}$.

ABSTRACT (ARABIC)

ملخص الرسالة

الاسم الكامل: محمد صلاح أحمد عبدالباسط

عنوان الرسالة: إدمصاص مركبات الكلوروميثان من الوسط المائي باستخدام الكربون المنشط/أكاسيد المعادن النانوية.

التخصص: كيمياء

تاريخ الدرجة العلمية: مايو 2014

لقد تم في هذا البحث تحضير أربعة أنواع جديدة من الممتزات وهي كما يلي: الكربون المنشط المشتق من مخلفات إطارات السيارات المستعملة ، الكربون المنشط/أكسيد الزنك النانوي، الكربون المنشط/أكسيد السليكون النانوي والكربون المنشط/أكسيد السيريوم النانوي. المرحلة الثانية هي اختبار مدي كفاءة هذه الممتزات في إمتزاز مركبات الكلوروميثان والتي تعتبر من الملوثات البيئية وبالتحديد تم إستخدام ثلاثة مركبات محضرة في الوسط المائي بتركيزات مختلفة وهي ثنائي كلوروميثان، ثلاثي كلوروميثان ورباعي كلوروميثان. إن الكربون المنشط ذو المسام النانوي تم تحضيره عبر عدة خطوات وهي التفكك الحراري في جو خامل من غاز الهليوم ومن تم التنشيط الفيزيائي واخيرا الكيميائي بواسطة بيروكسيد الهيدروجين وحمض النيتريك.

بالنسبة للممتزات الأخرى تم تحضيرها عن طريق الترسيب المشترك ومن ثم تسخين الناتج عند درجة حرارة عالية. هنالك عدة طرق تشخيصية استخدمت لتحديد شكل وتركيب الممتزات وأيضا الثبات الحراري. حركة الإدمصاص لقد تم دراستها ووجد أنها تتبع للرتبة الثانية الكاذبة كما تم دراسة أيزوثيرم الإدمصاص والنتائج خضعت للانغمور أيزوثيرم كما تم إعادة إستخدام الممتزات لثلاثة مرات وأعطت نفس الكفاءة الامتزازية. من خلال المقارنة بين الممتزات الأربعة وجد أن ترتيبها من حيث الكفاءة الإمتزازية كالآتي: ،الكربون المنشط/أكسيد السليكون النانوي < الكربون المنشط/أكسيد الزنك النانوي < الكربون المنشط/أكسيد السيريوم النانوي < الكربون المنشط.

CHAPTER 1

INTRODUCTION

Hazardous volatile organic compounds (VOCs) which are typically used as solvents, cleaning agents, coating agents, and extractants in different industries, are released from various chemical and pharmaceutical industries (J. Lemus, 2012). Chloromethanes are considered hazardous waste materials and are produced in large amounts for different applications (C. S.-F. B. de Rivas 2012). The proper disposal and monitoring of these compounds is of significant concern on the environment due to their stability, and the accumulation in of these compounds in the environment also contributes to the contamination of groundwater, which threatens living beings and can be considered dangerous and toxic organic pollutants ((ATSDR) 1997). Additionally, these compounds cause a depletion in the ozone layer of the atmosphere and act in conjunction with photochemical smog to increase global warming (E. Dobrzynska, 2010). Furthermore, the chloromethanes are used in large-scale quantities by industries and are then released as industrial effluent waste (Yu J.-J. C.-Y., 2000; Shawwa A. S., 2001) Most of the chloromethanes are classified as carcinogenic and toxic (R. Iranpour 2005). These compounds, when released into the environment via industrial exhausting gases or wastewater streams, present direct and serious impendence to all living organisms. Thus, it is important to eliminate these compounds before discarding the wastewater to the environment. Therefore, chloromethanes were classified as highly harmful compounds,

and the emission monitoring and regulation was begun by the U.S. Environmental Protection Agency. Adsorption technology is one of the most commonly used techniques in the elimination of chlorinated volatile organic compounds (Cl-VOCs). Activated carbon is most frequently used material among the different adsorbents due to large surface area, unique microporosity and low cost (Lillo-Ródenas et al 2005). Different methods for removal of Cl-VOCs have been reported. For example, cryogenic condensation (Gupta, 2002), biofiltration (Xie, 2009), wet absorption methods (Chungsiriporn, 2006) as well as catalytic oxidation (Palacio, 2010) and thermal oxidation connected with recuperation are a few example methods (Salvador, 2006). Volatile organic compounds (VOCs) are expressed by the US EPA as compounds which have high stability and possess a vapor pressure higher than 0.1 mmHg (13.332Pa) (Arjan Giaya 2000). Chloromethanes compounds are one of the VOCs containing at least one covalently bonded chlorine atom. The environmental pollution produced by industrial wastewaters from many industries including herbicide, pesticide, paint, solvent, pharmaceutical, pulp, and paper (Sonoyama 2001). The maximum solubility of dichloromethane ($17,220\text{mgL}^{-1}$) which is higher compared to the chloroform and carbon tetrachloride 8250 and 825 mgL^{-1} , respectively (Rexwinkel 1999). Chlorinated hydrocarbons are absorbed readily via the digestive system and lungs when breathed and transferred to body in the blood. They can be collected in the liver, kidneys, brain, or fatty tissues in short time. In liver, it changes into other compounds and finally passes out of the body. Generally most of these compounds are discarded from the body within few days after the exposure. High dosage was observed to cause dizziness, decrease the ability to concentrate and remember, damage the nervous system, and lead to an irregular

heart beat that are exposed in the work place and in laboratory animals (Parker 1997, V. Hecht 1995, R.F. Dunn 1994).

1.1 Statement of the problem

Many Cl-VOCs are harmful compounds to human health and the environment. The chloromethanes have been considered as contaminants for the ground water. These compounds must be monitored under serious environmental regulations due to their toxicity, carcinogenicity (J.W. Lee 2005). These compounds are also causes decaying of the stratospheric ozone layer, global warming and the photochemical smog formation, and the effect on human tissues (J. Pires 2001). As a results enhanced adsorption must be used by designing more efficient adsorbents.

1.2 Objectives of the study

- Development of some nanocomposits adsorbent prepared from activated carbon with some metal nanoparticles like ZnO/AC and CeO₂/AC. The activated carbon was prepared from waste materials.
- Characterization of the prepared adsorbents by using different analytical techniques like scanning electron microscope (SEM), (EDX), (TGA),(XRD) and spectroscopic characterization by FT-IR.
- Treatment of the chloromethanes (dichloromethane, chloroform and carbon tetrachloride) by the developed materials.
- Evaluating the performance by applying the kinetic order models and adsorption isotherm models such as Langmuir, Frundlich and Temkin isotherms.

1.3 The significance of the study

It is a worldwide problem nowadays to get a clean source of drinking water. Thus, this study will develop a process for water treatment. The focus will be on chloromethanes, mainly three compounds (dichloromethane, chloroform and carbon tetrachloride).

CHAPTER 2

LITERATURE REVIEW

Desalinated water it can be used for different purposes its use for drinking and other related domestic purposes. Thus, it is important to introduce a safe water supply. Chloromethanes have a wide applications in the chemical and pharmaceutical industries, they have been used as solvents and in aerosols, dry cleaning, adhesives, etc. (Z.M. de Pedro 2006). The toxicity of Cl-VOCs is related to their difficulty to biodegradation and, accumulation in the environment. They classified as carcinogenic or toxic and exhibit potential hazard under exposed (R. Iranpour 2005).

2.1 Methods for removal of chlorinated hydrocarbons

Depending on their concentration in water and on the usage of the treated water, different methods have been used for the removal of chloromethanes and their recycling treatment (V. Janda 2004). These methods include photocatalytic degradation, ultraviolet (UV) oxidation, biological treatment, air stripping, and thermal treatment (Jin Chul Joo 2013). Other methods for removal of Cl-VOCs have been reported, such as cryogenic condensation (Gupta 2002), biofiltration (Xie 2009), wet absorption methods (Chungsiriporn 2006) as well as catalytic oxidation (Palacio 2010) and thermal oxidation connected with recuperation (Salvador 2006). There are different porous materials that can be used as adsorbents like: zeolites (J. A. Pires 2002), clays (López-Cortés 2008), MCM-48 (W.G. Shim 2006), silica and spherical silicas (Hung 2009), organically

modified silica adsorbents and activated carbon from various precursors (Rafał Janus 2011).

Adsorption technology is one of the most widely used methods for the treatment of Cl-VOCs. (Lillo-Ródenas et al 2005). Adsorption by activated carbon provides high efficiency for the removal of organic, inorganic heavy metal ions, and volatile chlorinated hydrocarbons contaminants from industrial wastewater and drinking water (Sotelo 2002, Yun 1998). Nowadays, activated carbon is the most commonly used material for the removal of VOCs due to its high surface area, unique microporous structure, and low cost (Pan, 2013). The main method for the removal of chloromethanes is incineration, but the problem is producing other compounds which are more hazardous than the target contaminants, like phosgene, dioxins and furans (D. Verhulst et al 1996 , A. Buekens et al 1998). Different treatments are being investigated for the removal of chloromethanes, such as hydrodechlorination by using different kinds of the catalysts, like Pt or Pd. The hydrodechlorination with Pt or Pd method is promising due to the high conversions, but the deactivation of the catalyst is its limitation (Jesus Lemus 2012). Non-destructive techniques like adsorption, condensation and absorption are the most frequently applied for the removal/recovery of chloromethanes from gas streams (A. Anfruns 2011, X. Ren 2011).

2.2 Metal oxide nanoparticles

Metal oxides nanoparticles represent a high surface area with nano-sized building blocks (H. M. K. Yogesh Kumar 2013). The most important factors for these surfaces are the size and shape of nonionized metal oxides nanoparticles NMOsNPs, which can affect their adsorption efficiency. Many studies have been conducted on the synthesis of metal

oxide nanomaterials, and these studies managed to prepare nanomaterials which were of different shapes, highly stable, and nonagglomerated. There are two types of the methods for the synthesis : (1) physical methods, which include high-energy ball milling with severe plastic deformation and (2) chemical methods, including chemical vapor condensation, controlled chemical co-precipitation, pulse electrode position, liquid flame spray, liquid-phase reduction, gas-phase reduction, etc (L. Li 2006). In addition to the the widely used aforementioned techniques, others methods include co-precipitation (A.L. Willis 2005, B.L. Cushing 2004), thermal decomposition and/or reduction (J. Park 2004), and hydrothermal synthesis (X. Wang 2005), which produced the metal oxides nanoparticles with high yield percent (Y. Ju-Nam 2008).

2.2.1 Zinc oxide nanoparticles

Zinc oxide nanoparticles are environmentally friendly and have many applications in photocatalysis (H.B. Zeng 2008, G.H Chen 2008), gas sensors (Z.H. Jing et al 2008), solar cells (T.P. Chou 2007). As an adsorbent, ZnO has been primarily used for removal of H₂S. However, recently ZnO nanoparticles have been used with high efficiency in the removal of heavy metals (W. C. X.B. Wang 2010). For example, Lee et al, (J.H. Lee 2005) synthesized (ZnO) nanoparticles powder via “solution-combustion method (SCM)” which was tested on the removal of Cu²⁺ ions from the solution and resulted in high adsorption capacity. There are several different methods by which high surface area ZnO nanoparticles can be created, such as the following: hydrothermal (T.M. Shang 2007, F. Xu 2006 , X.L Cao 5267–5270), solvothermal (T. Ghoshal 2007), chemical vapor deposition (N. Zhang 2009, C. Xu 2006), electrochemical deposition (B.Q. Cao 2007 , B. Illy 2005), and microwave methods (Z.H. Jing et al 2008). ZnO

nanoplates exhibit properties like TiO_2 , and has advantages that include being an inexpensive material, easy preparation, and suitable to tailor morphologically (X.F. Ma 2010). More specifically, the solvothermal method for preparation of ZnO nanoplates (W. C. X.B. Wang 2010) contains two non-polar terminal planes with several micrometers in the planar direction and is 10–15 nm in thickness. To summarize, zinc oxide nanoparticles impregnated on activated carbon (ZnO-NP-AC) are non-toxic and thus suitable for being a “green” adsorbent (H.B. Senturk 2009).

2.2.2 Cerium oxide nanoparticles

Ceria is an inexpensive, nontoxic, and highly stable material. Therefore, ceria has been used as a component to prepare composite oxides (J.R. Xiao 2006, Y.H. Xu 2006). Ceria is a rare earth metal oxide which is commonly used in the industry as a catalyst, UV protectant, and in many applications as adsorbents, shielding materials, fuel cells, gas sensors, polishing materials, and luminescence (S. Yabe 2003, L.Y. Wang 2007, E.L. Brosha 2002). The adsorption capacity of ceria depends significantly on the surface morphologies, sizes, shapes, and areas. Ceria nanoparticles has shown new properties for catalytic activity (S. Carretin 2004), blue shift in absorption spectra (T. F. S. Tsunekawa 2000), lattice expansion (K. I. S. Tsunekawa 2000), phase transformation, and photovoltaic response (A. Corma 2004). Cerium oxide nanoparticles were prepared by converting Ce^{3+} to Ce^{4+} with an oxidizing agent under alkaline conditions and stabilized by hexamethylenetetramine (HMT) (F. Zhang 2004). During this process, CeO_2 nanocrystals can be stabilized by HMT which prevents agglomeration of nanoparticles through formation of double electrical layer. The mean size of the prepared material was 12 nm. The development of new synthesis

approaches and the application of highly dispersed cerium oxide nanoparticles on activated carbon materials has been studied intensively. Namely, CeO₂/AC composite was synthesized by the chemical co-precipitation through impregnation method with cerium nitrate salt (J.C. Serrano-Ruiz 2008, E. Ramos-Fernández 2008).

2.2.3 Silicon oxide nanoparticles

Silica is a widely available in the earth's crust, but it has low reactivity and thus, is limited in its direct use (Uhrlandt, 2006). On the other hand, the crystalline shape and microstructure of various silica products have many uses. The amorphous silica, which has high specific surface area (porous material with a small size of the particle), is widely used in many applications, such as absorbents, thermal insulators, and catalyst supports (J. L. Gurav 2010, GM 2003, Adam 2012). Furthermore, silica has unique properties due to its stability, possibility to be regenerated, fast equilibrium, high mechanical resistance, and high surface area; therefore it is considered distinguish adsorbents (A.R. Cestari, 2006), also it can decorated by different surface groups (M.A. Hassanien, 2006). Many studies have been conducted using functionalized silica materials as adsorbent in pollutant removal (V.K. Gupta S. , 2009 ; N.M. Mahmoodi, 2011).

Many studies produced silica nanoparticles, but a silicon source is needed as a precursor, and silicon alkoxides are a commonly used material for such a precursor (Soleimani Dorcheh 2008, Vivero-Escoto 2010). Silicon alkoxides (such as tetraethoxysilane) can be produced from the carbothermal reduction raw sand (RM Laine 1991, Rösch 2000). Silica nanoparticles are commonly used nanomaterial for many industrial applications such as, packaging, high-molecule composite materials, and ceramics production (Xifei Yang 2013). Silica nanoparticles can also be used as

hardening agent and in different medical applications because it is biocompatible and non-toxic (L. Yang 2013). The silica nanoparticles can be used as an impregnated medium for the synthesis of surface-modified silica, which means it works well as an adsorbent and high capacity cation exchange (J. Wang 2010 , R. Serna-Guerrero 2010).

2.3 Activated carbon

Adsorption is a highly efficient processes that can be used for removing certain organic and inorganic contaminants from wastewater. Carbonaceous adsorbents, like activated carbon and granular carbon, have been used in the treatment of the wastewater because it is a cost-effective material, has a high capacity of adsorption, and is generally available locally (Wang 2007). Due to the aforementioned properties, activated carbon has a applicable for industrial uses, especially in the water purification and industrial wastewater treatment (Jankowska 1991, Gonzalez-Serrano 2004). Furthermore, carbonaceous adsorbents are most commonly applied toward the treatment and removal of species from aqueous effluents. Additionally, granular activated carbons have been investigated for their ability to uptake volatile compounds and have been shown to be highly efficient at reducing the contaminants to undetectable levels, which prevents the disposal of harmful volatile compounds into the atmosphere (Stenzel 1995, Bansode 2003). Adsorption via activated carbon (AC) has been commonly used for the up taking of gaseous organic contaminants (P. Navarri, 2001; X. Zhang, 2011).

The ability of commercially available activated carbons (GAC 1240, GCN 1240, RB 1, pK 1-3, ROW 0.8 SUPRA) to remove chloromethanes from wastewater was investigated, and the best adsorbent was reported to be GAC 1240 granulated activated

carbon (Pavonia et al., 2006). Commercial activated carbon (CAC) has limitations for its usual as material that can be used for removal of environmental contaminants because of its high cost, and for this reason, researchers have developed cost-effective adsorbents and have investigated different raw starting materials (eg: bagasse sugar, starch xanthenes, sawdust of *Pinus sylvestris*, chitosan, bentonite, and discarded automobile tires) for activated carbon synthesis (C. J. V.K. Gupta 2003, W.S. Wan Ngah 2005, G. Bereket 1997, F. Calisir 2009). Tire rubber is one of the promising materials in the synthesis of activated carbon; it is composed from different elastomers, such as butadiene rubber, natural rubber, and styrene butadiene rubber besides other additives such as sulfur, carbon black, and zinc oxide (R. Murillo 2006). About 32% by mass of the rubber tire is the carbon black; therefore, the total carbon content between 70–75 wt % (B. G. V.K. Gupta 2011). Production of activated carbon from waste tires for aqueous phase treatment of contaminants has recently received more interest (Miguel 2002, Ariyadejwanich 2003, Hamadi 2004, Mui 2010).

CHAPTER 3

Experimental

3.1 Chemicals and materials

Three chloromethanes standards were used in this study: dichloromethane (CH_2Cl_2 , 99 %, 84.93 g/mol), chloroform (CHCl_3 , 99% , 119.38 g/mol) and carbon tetrachloride (CCl_4 , 99%, 153.82 g/mol). These chloromethane standards as well as the Zinc nitrate and ammonia were obtained from Sigma-Aldrich.

3.2 Preparation of the adsorbents

3.2.1 Preparation of Activated Carbon (AC)

The procedure for the synthesis of activated carbon (AC) from waste rubber tire material is explained by Gupta et al, (Vinod Kumar Gupta 2013). The waste of rubber tire was heated to 300 °C to isolate the black oil and yellow diesel oil. Then, the granules were carbonized by thermal pyrolysis under helium gas at 500°C for 3h. The carbonaceous material was heated with steam at 900°C for 2h to develop its porosity system. The chemical activation was performed via HNO_3 and H_2O_2 treatment in order to develop oxygen groups on the surface of the material. The carbonaceous material was treated with HNO_3 (4M concentration) with a ratio of 1g of carbon to 20 mL of HNO_3 and then heated at 60°C for 24h. Next, the product was washed and dried at 100°C and then followed by

treatment by H_2O_2 (6%) with a ratio of 1 g/20mL carbon/ H_2O_2 . Again, it was washed and dried at 100°C .

3.2.2 Preparation of ZnO-NP/AC

ZnO nanoparticles loaded with AC were prepared via thermal co-precipitation. 6.0g of the prepared AC was suspended in 150 mL of deionized water and dispersed with a sonicator. A 6.975g of $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ was dissolved in 50 mL of deionized water and then added gradually to the previous mixture. The mixture was stirred for 2h. The pH of the mixture was adjusted between 8-9. Next, that the solution was refluxed at 90°C for 6h with constant stirring. The precipitate was collected by filtration and then washed and dried at 110°C overnight. The composite was calcined at 350°C for 4h.

3.2.3 Preparation of SiO_2 -NP/AC

The composite of SiO_2 -NP/AC was prepared via co-precipitation method. 6.0g of AC was dispersed in 150mL of suitable media by the use of sonicator. A 50mL solution containing 3.8g of sodium meta silicate was prepared and then added drop-wise into the AC mixture. This new mixture was stirred for 24h at 50°C . The mixture was pH-controlled while being heated under reflux at 90°C for 12h with stirring. The precipitate was then cooled, filtered, washed and dried at 110°C overnight. The product was calcined at 350°C for 4h.

3.3 Characterization of the adsorbents

The characterization of the adsorbents was achieved by using a combination of various techniques and analyses, which included: 1. scanning electron microscope (SEM) to show the morphology of the developed adsorbents, 2. energy dispersive X-ray

spectroscopy (EDX) and X-ray diffraction spectroscopy (XRD) for compositional analysis, and 3. thermogravimetric analysis (TGA) to reflect the physical and chemical structure changes during the conversion and to provide thermal stability information. Some spectroscopic techniques like infrared spectroscopy were used to determine the functional groups present on the surface of the adsorbents.

3.3.1 Fourier Transform Infrared spectroscopy (FT-IR)

FT-IR (Nicolet 6700 spectrometer-Thermo electron, USA) was provided by OMNIC software, and verified with a deuterated triglycine sulfate (DTGS) detector. The samples were prepared via the solid KBr pellet techniques, and the spectra were obtained by using the transmittance mode with wave number over range between ($4000\text{--}400\text{ cm}^{-1}$). The background correction of the spectra was performed by 16 scans with resolution 2 cm^{-1} for the correction of background noise.

3.3.2 Field Emission Scanning Electron Microscope (FE-SEM)

Field emission scanning electron microscope (TESCAN LYRA 3 FEG) model was used for identification of the surface morphology and nanostructure of the prepared adsorbents.

3.3.3 Energy Dispersive X-ray Analysis (EDX)

Energy dispersive X-ray spectroscopy (EDX) instrument model (Oxford-England and X-Max detector) was used for the determination of the chemical composition of the adsorbents.

3.3.4 X-ray Diffraction Analysis (XRD)

X-ray diffraction results were obtained by using (Shimadzu XRD Model 6000, Japan) diffractometer (K α radiation of Cu); the instrument was operated at 40kV and 30mA.

3.3.5 Thermogravimetric Analysis (TGA)

Thermogravimetric analysis was performed using SDT analyzer (Q 600) that is manufactured by TA instruments (USA). The sample being tested (usually 6mg) was placed in an aluminum crucible. The temperature was raised at a uniform rate of 15°C/min. The analyses were made over a temperature range of 20–900°C in a nitrogen atmosphere flowing at a rate of 50 ml/min.

3.4 Batch sorption procedure

The equilibrium adsorption isotherm was studied by using batch adsorption procedures. These batch equilibrium studies were conducted by using the composite materials within a solution of chlorinated hydrocarbons in a series of 125mL conical, airtight Pyrex glass flasks. A few different parameters were recorded, such as 1. the effect of the composite dosage in a range between (0.25-5 g/L), and 2. the effect of initial concentration and contact time. Each flask contained 50ml of a chlorinated hydrocarbons solution with the desired pH and temperature being adjusted. A predetermined amount of the composite was added to each flask and placed in an isothermal shaker at 150 rpm until equilibrium was achieved. The chlorinated hydrocarbon adsorption at a certain time, t , (q_t , mg/g) was identified by equation (1):

$$q_t = (C_o - C_t) \times \frac{V}{m} \quad (3.1)$$

Where V is the volume of chlorinated hydrocarbons solution in liters, C_o (mg/L) and C_t (mg/L) are the initial and final concentrations at time t of chlorinated hydrocarbons in solution, respectively and m (grams) is the weight of adsorbent.

3.5 Data analysis

The data were collected from the batch study at different adsorbent dosages, and concentrations (20,10,5 ppm) were analyzed by using kinetic study and applying (pseudo-first order, pseudo-second order and intra-particle diffusion). Also, different adsorption isotherm models were conducted (Langmuir isotherm, Freundlich isotherm and Temkin isotherm) to identify the adsorption capacity.

3.6 Analysis of chloromethanes

The analysis of chlorinated hydrocarbons was carried out by using the Headspace Gas Chromatography Mass Spectrometer (HS-GC/MS). Sample analysis was conducted by using an Agilent 7890A GC interfaced with an Agilent 5975C network mass selective detector. Direct headspace automated injection was performed by using 2.5 ml-HS syringe with and injection of 250 μ L of the headspace vapor. The incubation temperature was optimized in the range between 40-70°C for 1-20min, and the optimum temperature and time were found to be 60°C and 15 min respectively. Additionally, 10 ml vials were used, and the optimum volume was found to be 1mL. The agitation speed was 250 rpm, syringe temperature 50°C, and the injection speed was 500 μ L/sec. GC-MS conditions were optimized and adjusted, as measured by maximum sensitivity, according to the baseline separation of analyte and Gaussian peak shapes. The inlet of the GC was operated in split 50:1 mode at 180°C. The oven temperature program was as follows:

35 °C for 10 min, then increased at a rate of 5 °C/min to 40 °C for 1 min, then 15 °C/min to 120 °C for 2 min, then 20 °C /min held at 120 °C for 11 min (total run time 17.33min). The helium was maintained at a constant flow of 1.4 ml/min by using a capillary column, HP-5 (5% phenyl methyl siloxan) 30m x 320 µm x 0.25 µm. The analytes were determined by using a mass spectrometer in electron impact (EI) ionization mode at 70 eV. The mass spectrometer quadrupole temperature was set at 150 °C and the mass spectrometer source at 230 °C. Optimization experiments were performed in total ion chromatogram (TIC) mode between m/z 40 and 550. Quantification of dichloromethane, trichloromethane, and carbon tetrachloride were performed in selected ion monitoring (SIM) mode, and suitable fragments of the compounds were (the base peaks used for quantification are boldfaced): 49,84,86,88 for dichloromethane; 83,85,47 m/z for trichloromethane and 117,119,121,82 m/z for carbon tetrachloride.

3.7 Desorption and regeneration of the adsorbents

Desorption experiments were performed in batch equilibrium procedure as well. All of the experiments started by dispersing used adsorbent 0.1gram into 50 ml of 10ppm chlorinated hydrocarbons mixture after evaporation of the adsorped molecules at 100 °C for 24 hours and then agitating at 25 °C for 120 min with agitation speed 150 rpm for which three recycles were done by repeating the same procedure.

CHAPTER 4

Sorption by activated carbon

4.1 Characterization of activated carbon

Fourier transform infrared spectroscopy fig (4.1) is the most useful technique to identify the presence of a functional group in the prepared material. The band located around 1640 cm^{-1} represents the enhancement in the aromatic C=C groups (carbonization). The broad band at 3400 cm^{-1} represent O-H mode, and the band at 2900 cm^{-1} is C-H aliphatic mode. Lastly, the band at 1054 cm^{-1} is representative of the C-O stretching vibration. The activated carbon morphology was investigated by SEM technique fig (4.2). The SEM image illustrates the porosity of the activated carbon. The image shows two different morphologies. One of them is granular in its structure ($0.5\mu\text{m}$ in diameter). High resolution shows different pore structures on the surface of the adsorbent. EDX analysis was conducted to identify the chemical composition of the adsorbent. The spectrum in fig (4.3) illustrates the presence of carbon and oxygen in the rubber tires carbon. Table (4.1) shows the EDX analysis of prepared activated carbon. The XRD pattern of the carbon exhibits a weak diffraction peak, which can be attributed to the aromatic carbon sheets fig (4.4). The thermal stability was examined by TGA analysis under nitrogen gas as shown in fig (4.5), which shows that the material was stable up to 400°C .

4.2 Effect of activated carbon dosage and contact time

Adsorbent dosage has a significant effect on the efficiency of the adsorption, depending on the initial concentration of the adsorbate. The effect of activated carbon dose on the adsorption of chlorinated hydrocarbons is illustrated in fig (4.6). Different adsorbent dosages were applied for dichloromethane, trichloromethane, and carbon tetrachloride at initial concentrations 2.0,1.0,0.5 mg/L respectively, at 25°C with a shaking time of 60 min. Results show that as the adsorbent dosage increased, the percent removal of chlorinated hydrocarbons was increased from 45.35% to 86.96% for dichloromethane, from 79.65% to 98.13% for chloroform and from 95.90% to 99.80% for carbon tetrachloride, with an increase in the amount of adsorbent from 0.5 to 5.0 g/L. This can be attributed to the increase in surface area with an increase in adsorbent amount for a certain concentration of chlorinated hydrocarbons. It can be clearly seen that the increase in chlorinated hydrocarbons removal percentage increases dramatically when the adsorbent mass increase from 0.5 to 5.0 g/L. Finally, the increase of percent removal of chlorinated hydrocarbons was slow when activated carbon dose was greater than 5.0 g/L because some parts of active sites have become saturated by chlorinated hydrocarbons, which diminishes the adsorption process and results in a lower adsorption capacity (Ali 2013). It is obvious from fig (4.7) that the adsorbed amount of chloromethanes was increased by increasing the contact time. Therefore, the adsorption was very fast in the first 10 min and then decrease to a constant at the equilibrium point. The time of saturation is almost reached at 20 min. The percent removal of chlorinated hydrocarbons in solution is calculated by Eq (4.1) as follow:

$$\% \text{ Removal} = \frac{C_o - C_e}{C_o} \times 100 \quad (4.1)$$

Figure 4. 6 Effect of adsorbent dosage on the adsorption of dichloromethane, trichloromethane and carbon tetrachloride, time 20 min, temperature 25°C.

Figure 4. 7 Effect of contact time on adsorption of (a) dichloromethane, (b) trichloromethane and (c) carbon tetrachloride at different AC dosage and temperature 25°C.

4.3 The pseudo-first-order model

The pseudo-first-order kinetic model is generally used to express the adsorption kinetics for solid-liquid systems (A. A. B.H. Hameed 2007). It is expressed as:

$$\log(q_e - q_t) = \log q_e - \frac{k_1}{2.303} t \quad (4.2)$$

Where k_1 is the Lagergren rate constant (1/min), q_e and q_t are the quantity of chlorinated hydrocarbons (mg/g) at contact time t and at equilibrium, respectively. The plots of $\log(q_e - q_t)$ versus t illustrated in fig (4.8) give the values of the rate constant k_1 and adsorption quantity q_e at equilibrium, which were calculated from the slopes and intercepts, and table (4.2) illustrates these values. The correlation coefficients (R^2) were low for different adsorbent dosages, which illustrates bad linearity. The agreement between the calculated q_e from the equation (4.2) and observed q_e is very poor. These results demonstrate that the adsorption process of chlorinated hydrocarbons does not fit well to the pseudo-first-order kinetic equation and that the mechanism of the adsorption may not obey the pseudo-first-order model.

Figure 4. 8 Lagergren first order plot for adsorption of (a) dichloromethane,(b) trichloromethane and (c) carbon tetrachloride at different AC dosage and temperature 25°C.

4.4 The pseudo-second-order kinetics

The adsorption kinetic of pseudo second-order is described as (M. S. Chiou 2002, Y. S. Ho 2001, S. P. Karthikeyan 2008):

$$\frac{dq_t}{dt} = k_2(q_e - q_t)^2 \quad (4.3)$$

Where k_2 is the rate constant (g/mg.min), and q_e and q_t are the amount of adsorbate in milligram per gram of the adsorbent at equilibrium and time t , respectively. By applying the integration at the boundary conditions $t=0$ to $t=t$ and $q_t=0$ to $q_t=q_e$, the form of the equation (4.3) becomes:

$$\frac{1}{q_e - q_t} = \frac{1}{q_e} + k_2 t \quad (4.4)$$

Equation (4.4) represents the pseudo-second-order equation in its integrated form and can be written in the linear form as below :

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (4.5)$$

Where h is the initial adsorption rate at $t = 0$, h (mg/g.min) can be described as :

$$h = k_2 q_e^2 \quad (4.6)$$

Therefore equation (4.6) can be written in a form as:

$$\frac{t}{q_t} = \frac{1}{h} + \frac{t}{q_e} \quad (4.7)$$

According to the above equation, the plots of t/q_e against t produced linear plots fig (4.9). Different parameters of the adsorption, such as q_e , cal, and k_2 were calculated from the intercepts and slopes of the plots, respectively which are shown in table (4.2). The correlation coefficients (R^2) of the linear regression were higher than 0.99 for all adsorbent dosages. Additionally, the expected equilibrium adsorption capacities (q_e , cal) calculated from Eq (4.5) coincided very well with the experimental equilibrium adsorption capacities. These results demonstrate the that fit of the experimental data to is as expected based on all of the aforementioned equations and expected equilibriums (Y. Nuhoglu 2009).

Figure 4. 9 Linear regression of kinetics Plot: pseudo second order for (a)dichloromethane, (b)trichloromethane and (c) carbon tetrachloride at different AC dosage and temperature 25°C.

4.5 The intraparticle diffusion model

The Weber and Morris model is a typically used to determine the rate controlling step (L. Wang 2010, W.J. Weber 1963). The rate constants of intra-particle diffusion (k_{id}) can be investigated by using the following equation:

$$q_t = k_{id}t^{1/2} + C \quad (4.8)$$

Where q_t is the amount adsorbed chlorinated hydrocarbons at time t , $t^{1/2}$ is the square root of the time, C is the intercept. The value of C refers to the thickness of the boundary layer. The plots of q_t versus $t^{1/2}$ at different adsorbent dosages show multilinearity characterizations fig (4.10).The lines of the different concentrations do not go through the point of origin, which means the mechanism did not elucidate the rate of the overall

process and that there is a complicated mechanism underlying the adsorption and intra-particle diffusion (G. Cunha 2010).

Figure 4. 10 Intraparticle diffusion kinetic plot for (a) dichloromethane, (b) trichloromethane and (c) carbon tetrachloride at different AC dosage and temperature 25°C.

Table 4. 2 Kinetic constant parameters obtained for chlorinated hydrocarbons adsorption on AC.

4.6 Adsorption isotherm

The adsorption isotherm describes the adsorption process in terms of the interaction between the molecules in the solution of the adsorbate and the adsorbent when the adsorption process is in the equilibrium stage (Hameed 2006).

4.6.1 Langmuir isotherm model

The Langmuir adsorption model is given by:

$$\frac{C_e}{q_e} = \frac{1}{k_L q_m} + \frac{C_e}{q_m} \quad (4.9)$$

Where K_L is Langmuir equilibrium constant (liters/miligrams), and q_m (mg/g) is the maximum adsorption capacity produced by monolayer of adsorbate. The parameters can be calculated from a plot C_e/q_e versus C_e fig (4.11). The most important parameter of Langmuir equation is the separation factor, R_L , defined by Weber and Chakkravorti (Weber T.W. 1974):

$$R_L = \frac{1}{1 + K_L C_o} \quad (4.10)$$

Where C_o is the highest initial concentration of the solute. The value of separation factor gives an indication for the type of the isotherm. Considering the R_L value, adsorption is defined as either being unfavorable ($R_L > 0$), linear ($R_L = 1$), favorable ($0 < R_L < 1$) or irreversible ($R_L = 0$) (S. Karagoz 2008). In our study, the R_L values were 0.0118, 0.1869 and 0.1645 for dichloromethane, chloroform, and carbon tetrachloride, respectively, and these values confirmed that the prepared activated carbon from the rubber waste material exhibits the expected favorable adsorption for these compounds.

Figure 4. 11 Langmuir model for adsorption of (a) dichloromethane, (b) trichloromethane and (c) carbon tetrachloride at different AC dosage and temperature 25°C.

4.6.2 Freundlich isotherm model

The Freundlich model is a theoretical equation can be applied to the adsorption on a heterogeneous surface of an adsorbent. The well-known Freundlich model as described by the logarithmic form is defined by the following equation:

$$\ln q_e = \ln K_f + \frac{1}{n} \ln C_e \quad (4.11)$$

Where k_F (L/g) is the adsorption capacity and, n is adsorption intensity, respectively. The plot of $\ln(q_e)$ versus $\ln(C_e)$ is shown in fig (4.12). The values of Freundlich parameters were determined and listed in table (4.3). The correlation coefficients, R^2 , indicate that the adsorption isotherm data follow the Freundlich model well. The calculated n values from the slope indicate the adsorption capacity. Generally, when the values of n fall in the range from 2 to 10, it is a good adsorption indicator. However, those values that range from, 1-2 are moderate, and less than 1 are poor adsorption characteristics. Our n values were between 1 and 2, which indicated that the adsorption is moderate.

Figure 4. 12 Langmuir model for adsorption of (a) dichloromethane, (b) trichloromethane and (c) carbon tetrachloride at different AC dosage and temperature 25°C.

4.6.3 Temkin isotherm model

The Temkin isotherm model exhibits the total amount of heat of the molecules in one layer on the surface of the adsorbent during the adsorption process. The linear decrease of adsorbent with coverage is referred to as adsorbent-adsorbate interaction. The linear form of the Temkin model is expressed as:

$$\ln q_e = \frac{RT}{b_T} \ln K_T + \frac{RT}{b_T} \ln C_e \quad (4.12)$$

Where b_T is the Temkin constant and is related to the heat of sorption (kilojoules per mole). The k_T parameter is the equilibrium binding constant, which is equal to the maximum binding energy (L/g), and R is the universal gas constant (8.314×10^{-3}). T is the absolute temperature (degrees Kelvin) (Mohd Nazri Idrisa 2011). The isotherm parameters for the adsorption of the chlorinated hydrocarbons are given in table (4.3). The correlation coefficient, R^2 , for q_e versus $\ln(C_e)$ shows that the Temkin isotherm does not flow the adsorption data.

.

Table 4.3 parameters of the Langmuir , Freundlich and Temkin models for adsorption of dichloromethane, chloroform and carbon tetrachloride at different AC dosage and temperature 25°C.

CHAPTER 5

Sorption by ZnO-NP/AC

5.1 Characterization of ZnO-NP/AC

The shape and surface morphology of the ZnO-NP/AC nanoparticles were investigated with scanning electron microscope (SEM), fig (5.1). The SEM images indicate the homogeneous and relatively smooth surface of the activated carbon that had been loaded with ZnO nanoparticles. The EDX analysis, fig (5.2), of the ZnO-NP/AC composite reveals that the composition of the nanoparticles corresponds to zinc and oxygen elements as in table (5.1). BET surface area of ZnO-NP/AC was found to be $15 \text{ m}^2/\text{g}$ with pore size of $0.3 \text{ cm}^3/\text{g}$ and adsorption average pore width of 802 \AA . The low specific surface area and total pore volumes could be due to the loading of ZnO nanoparticles on the carbon surface. Fourier transform infrared spectroscopy fig (5.4) is the useful technique to identify the presence of functional group in the prepared material. The band laying around 1640 cm^{-1} represents the enhancement in the aromatic C=C groups (carbonization). The strong and broad band at 3400 cm^{-1} represent O–H mode, and the band at 2900 cm^{-1} is C–H aliphatic mode. The band at 1054 cm^{-1} can be attributed to C–O stretching vibration. In addition to the previously mentioned bands, there is a band at 490 cm^{-1} that may be attributed to the stretching vibrational mode of

ZnO. The TGA analysis fig (5.5) shows the enhancement of the thermal stability of ZnO-NP/AC.

5.2 Effect of contact time and initial concentration

The adsorption profile of chlorinated hydrocarbons can be described by the effect of contact time by using ZnO-NP/AC (derived from rubber tires waste) composite at three different initial concentrations and is illustrated in fig (5.6). It can be clearly seen that the adsorption of chlorinated hydrocarbons rapidly increased with the increasing of contact time, and then decreased until the equilibrium was achieved. The resulting rate is related to the adsorption process because it takes place by fast rate at the initial step and is then followed by a slower internal diffusion process (Gialamoudis D. 2010). The fast adsorption at the initial step is due to the presence of a large number of vacant active sites, but after a lapse of time, the unoccupied surface sites cannot accommodate the solute molecules. This can be attributed to the repulsion between the solute molecules of the solid and bulk solution phases, so it takes a long time to reach the equilibrium. When the initial concentration is increased, the difference between the amount of the adsorbates of the solution and adsorbent phases increases because of increasing the driving force for mass transfer between the phases (Srivastava 2005). The adsorption capacity of chlorinated hydrocarbons after 10 min increased from 2.11 to 6.67 mg/g for dichloromethane, 4.67 to 11.91 mg/g for chloroform and from 3.60 to 16.10 mg/g for carbon tetrachloride as the initial chlorinated hydrocarbons concentration was increased from 5 to 20 mg/L. Therefore the adsorption was rapid in the first 10 min and then decreased until the equilibrium point. The time until saturation is nearly 20 min.

Figure 5. 6 Effect of contact time on adsorption of (a) dichloromethane, (b) chloroform, (c) carbon tetrachloride at different concentrations, and temperature 25°C.

5.3 Effect of adsorbent dosage

The amount of the adsorbent is a significant factor because it determines the efficiency of an adsorbent (Ouazene N 2010). The effect of ZnO-NP/AC dosage on the adsorption of chlorinated hydrocarbons is illustrated in fig (5.7). Different adsorbent dosages were applied for dichloromethane, chloroform and carbon tetrachloride with initial concentration 10 mg/L at 25°C and shaking for 60 min. The results indicate that as the adsorbent dosage increased, the percent removal of chlorinated hydrocarbons was increased from 32.24 % to 85.01 % for dichloromethane , from 80.72% to 99.4 % for chloroform and from 81.56% to 95.41 % for carbon tetrachloride with an increase in adsorbent dosage from 0.25 to 5.00 g/L. These results can be explained by the large surface area that results from an increase in the adsorbent amount or higher adsorption vacant sites for a constant concentration of chlorinated hydrocarbons (Panda L 2011, Zhang H 2010). It has been found that the increase in percent removal of chlorinated hydrocarbons was slow when the adsorbent dose was over 3 g/L (P. R. Gupta VK 2003, M. A. Gupta VK 2006). The percent removal of chlorinated hydrocarbons in solution is calculated by Eq. (5.1) as follow:

$$\% \text{ Removal} = \frac{C_o - C_e}{C_o} \times 100 \quad (5.1)$$

Figure 5. 7 Effect of adsorbent dosage on the adsorption of dichloromethane, chloroform and carbon tetrachloride at different adsorbent dosage, and temperature 25°C.

5.4 Adsorption kinetics

Adsorption kinetics illustrates the interaction between solid-solution interface, and it can determine the mechanism of the reactions. In order to estimate the adsorption mechanism, the following three models can be applied: the pseudo first-order, the pseudo second-order rate equation, and finally, the intraparticle diffusion models (Singh VK 1997, Ho YS 2000, Srivastava SK 1995). The correspondence between the adsorption data and the model expected values was represented by the values of correlation coefficient (R^2).

5.4.1 The pseudo-first order model

The pseudo-first-order kinetic model is a common model applied for understanding the mechanisms of solid liquid system (A. A. B.H. Hameed 2007). It is expressed as:

$$\log(q_e - q_t) = \frac{k_1}{2.303} t \quad (5.2)$$

Where k_1 is the Lagergren rate constant (1/min), and q_e and q_t are the quantity of chlorinated hydrocarbons (mg/g) at contact time t and at equilibrium, respectively. The plots of $\log(q_e - q_t)$ versus t demonstrated in fig (5.8), give the values of the rate constant k_1 and adsorption quantity q_e at equilibrium, which were calculated from the slopes and intercepts table (5.2). The correlation coefficients (R^2) were low for different concentration, illustrating bad linearity. The correspondence between the calculated q_e from the equation (5.2) and observed q_e were very poor. This demonstrated that the adsorption of chlorinated hydrocarbons deviated from this model and the mechanism of the adsorption on the surface of the ZnO-NP/AC may not fit the pseudo-first-order model.

Figure 5. 8 Lagergren first order plot for adsorption of (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations and temperature 25°C.

5.4.2 The pseudo-second order model

The pseudo second-order kinetic rate equation of the adsorption is expressed as (M. S. Chiou 2002 , Y. S. Ho 2001, S. S. Karthikeyan 2008):

$$\frac{dq_t}{dt} = k_2(q_e - q_t)^2 \quad (5.3)$$

Where k_2 is the rate constant (g/mg.min) , q_e and q_t are the adsorption capacity at equilibrium and time t respectively. By applying the integration at the boundary conditions $t=0$ to $t=t$ and $q_t=0$ to $q_t=q_e$, the form of the equation (5.3) becomes:

$$\frac{1}{q_e - q_t} = \frac{1}{q_e} + k_2 t \quad (5.4)$$

Equation (5.4) can be written as below:

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (5.5)$$

Where h is the initial adsorption rate at $t = 0$, h (mg/g.min) can be described as :

$$h = k_2 q_e^2 \quad (5.6)$$

Therefore equation (5.6) can be written in a form as:

$$\frac{t}{q_t} = \frac{1}{h} + \frac{t}{q_e} \quad (5.7)$$

The plots of t/q_t against t of equation (5.7) at different concentrations of the chlorinated hydrocarbons are illustrated in fig (5.9). The adsorption parameter q_e , cal and k_2 were calculated from the slope and the intercept, respectively table (5.2). The high linearity of the plots indicated by the correlation coefficient values (R^2) (> 0.99) means that the adsorption kinetics between ZnO-NP/AC composite and the chlorinated hydrocarbons belong to the pseudo-second order. In addition, the correspondence between the q_e , cal and q_e , gives further evidence for the fitting of the adsorption data, meaning that that the

adsorption rate of chlorinated hydrocarbons adsorption seems to be controlled by a chemisorption mechanism through the sharing of electrons or by covalent bonds between the surface of adsorbent and adsorbate (Y. Nuhoglu 2009).

Figure 5. 9 Linear regression of kinetics Plot: pseudo second order for (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations and temperature 25°C.

5.4.3 The intraparticle diffusion model

Weber and Morris model is a usually used applied to predict the intra-particle diffusion rate controlling step (L. Wang 2010, W.J. Weber 1963). The rate constants (k_{id}) can be determined by using the following equation:

$$q_t = k_{id}t^{\frac{1}{2}} + C \quad (5.8)$$

The plots of q_t versus $t^{1/2}$ are illustrated in fig (5.10). The lines of the different concentration do not go through the origin, which means the mechanism does not determine the rate of the overall process, and there must therefore exist a complicated mechanism included in adsorption and intra-particle diffusion (G. Cunha 2010).

Figure 5. 10 Intraparticle diffusion kinetic plot for (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations and temperature 25°C.

5.5 Adsorption isotherm

The adsorption isotherm describes the adsorption process in terms of the partition of adsorbate molecules between the two phases of adsorbent and the solution of the adsorbate at the equilibrium stage (Hameed 2006). Several isotherm models were used for investigation of adsorption capacity in adsorption of chlorinated hydrocarbon from aqueous solution. The three models were introduced in this study are Langmuir, Freundlich, and Temkin isotherms.

5.5.1 Langmuir isotherm model

The Langmuir assumes that the adsorption process occurs between a homogeneous adsorbent that has a certain active sites, energies, and monolayer of adsorbate. The linear equation is given by:

$$\frac{C_e}{q_e} = \frac{1}{K_L q_m} + \frac{C_e}{q_m} \quad (5.9)$$

Where K_L is Langmuir equilibrium constant (L/mg), and q_m (mg/g) is the maximum amount of the monolayer adsorbate in the adsorbent. They are calculated from a plot of C_e/q_e versus C_e fig (5.11). The Langmuir model can be characterized by R_L , known as the separation factor and defined by Weber and Chakkravorti:

$$R_L = \frac{1}{1 + K_L C_o} \quad (5.10)$$

The plots of C_e/q_e versus C_e shows high linearity which is confirmed by the correlation coefficient values in which $R^2 > 0.99$, thus giving indication that the isotherm data fit this model well. The Langmuir parameters were calculated and listed in table (5.3).

Figure 5. 11 Langmuir model for adsorption of (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations, and temperature 25°C.

5.5.2 Freundlich isotherm model

The Freundlich model is an empirical equation and that considers how the adsorption process occurs on heterogeneous surface of an adsorbent (Freundlich 1906). The Freundlich equation is defined by the following:

$$\ln q_e = \ln K_f + \frac{1}{n} \ln C_e \quad (5.11)$$

Where k_F (L/g) and n are the adsorption capacity and adsorption intensity, respectively., and can be obtained by plotting $\ln q_e$ versus $\ln C_e$ fig (5.12). The Freundlich isotherm constants K_F and n were calculated table (5.3). The n values gives an indication for the favorability of the adsorption process. The values of $n > 1$ represent favorable adsorption conditions (Treybal 1968, V.J.P. Poots 1978, Y.S. Ho 1998). The values of the correlation coefficient of Freundlich indicate that the linearity is very poor.

Figure 5. 12 Freundlich model for adsorption of (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations, and temperature 25°C.

5.5.3 Temkin isotherm model

The Temkin isotherm represents the quantity of heat generated in the adsorption by one layer on the surface of adsorbent. This heat can decrease linearly with coverage, and that referred to adsorbent-adsorbate interaction. The linear form of Temkin model is given by:

$$\ln q_e = \frac{RT}{b_T} \ln K_T + \frac{RT}{b_T} \ln C_e \quad (5.12)$$

Where b_T is the Temkin constant and is related to the heat of sorption (kJ/mol), K_T is the equilibrium binding constant, which is equal to the maximum binding energy (L/g), R is universal gas constant (8.314×10^{-3}), and T is the absolute temperature (degrees Kelvin) (M. Idrisa 2011). The plot of q_e versus $\ln C_e$ is illustrated in fig (5.13), and the isotherm constants were calculated from the slope and intercept table (5.3).

Table 5. 3 Langmuir, Freundlich, and Temkin isotherm constants for chlorinated hydrocarbon adsorption on ZnO–NP/AC.

Figure 5. 13 Temkin model for adsorption of (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations, and temperature 25°C.

5.6 Regeneration of the adsorbent

Adsorbent has limited capacity for adsorbate molecules, and at the equilibrium in the adsorption process, the rates of adsorption and desorption are equal, where the net uptaking of the adsorbate on the adsorbent cannot increase further. Thus, it is necessary either to dispose or regenerate the adsorbent. In the present study, the feasibility of adsorbent regeneration was examined with a chemical and thermal treatment. The chemical treatment was tested using solvent, and the thermal treatment was conducting by heating the adsorbent/adsorbate up to 120°C. The material was tested for three cycles, and the results showed excellent re-generability with almost the same percentage of removal. The results presented in fig (5.14), indicate that the prepared adsorbent is of excellent desorption and regeneration nature within acceptable experimental errors.

Figure 5. 14 Regenatration adsorption of (a) dichloromethane (b) chloroform (c) carbon tetrachloride at ZnO-NP/AC dosage 0.1 g/L, contact time 60 min, and temperature 25°C

CHAPTER 6

Sorption by SiO₂-NP/AC

6.1 Characterization of SiO₂-NP/AC

The morphology of SiO₂-NP/AC composite is presented in fig (6.3). As shown, the surface of the composite is rough and has large amount of nanoparticles, which represents additional active sites for surface adsorption on the activated carbon surface. Using the scale of the SEM image, one may estimate the average diameter of the silica particles as approximately 50 nm. This value has been confirmed by taking more images and by taking the average of the nanoparticles on each image. The EDX spectrum presented in fig (6.4) indicates the elements presented in the composite, i.e. carbon, oxygen, silicon and sodium. Thermal stability of SiO₂-NP/AC composite was also evaluated. Thermogravimetric analysis of the prepared composites is very important for identification of the thermal stability and optimal conditions of calcination. In fig (6.2) example of TGA curve collected for the sample in flowing nitrogen is presented. As it is shown, SiO₂-NP/AC has better thermal stability than pristine activated carbon (AC). The FT-IR spectrum of SiO₂-NP/AC composite is depicted in fig (6.1). The spectra of pristine AC and pristine silica were obtained for comparison. The characteristic adsorption bands of silicon dioxide, such as the Si–O–Si asymmetric and symmetric stretching vibration at 1080 and almost 800 cm⁻¹, respectively, and the O–Si–O symmetric bending vibration at

470 cm^{-1} . Also, the band at 1720 cm^{-1} corresponds to stretching vibration of C=O in carboxyl group on the activated carbon surface. Through comparing the FT-IR spectra of $\text{SiO}_2\text{-NP/AC}$ composite and that of AC and silica, it can be observed that some functional groups have been introduced into the surface of the prepared composite. This may help explain the enhanced absorption character of the $\text{SiO}_2\text{-NP/AC}$ composite. The XRD patterns of $\text{SiO}_2\text{-NP/AC}$ composite is depicted in fig (6.5). At low diffraction angles, the typical broad diffraction band of amorphous silicon dioxide can be observed. The XRD pattern of the carbon exhibits a weak diffraction peak that is attributed to the aromatic carbon sheets oriented in a considerably random fashion.

Figure 6. 1 FT-IR spectrum of the $\text{SiO}_2\text{-NP/AC}$

Figure 6. 2 TGA analysis of SiO₂-NP/AC.

Figure 6. 3 SEM image of SiO₂-NP/AC.

Figure 6. 4 EDX analysis of SiO₂-NP/AC.

Figure 6. 5 XRD pattern of SiO₂-NP/AC.

6.2 Effect of contact time and initial concentration

The effect of contact time on the removal capacity of chlorinated hydrocarbons by using $\text{SiO}_2\text{-NP/AC}$ (derived from rubber tires waste) composite at different three initial concentrations and constant dosage is shown in fig (6.6). It illustrates the adsorption profile of chlorinated hydrocarbons increased sharply with a contact time and then progressed by slower rate until it reaches the equilibrium step. This result is attributed to the large vacant active sites, for this reason the initial step of the adsorption it was very fast followed by slower internal diffusion process (Gialamouidis D. 2010). However, the quantity of chlorinated hydrocarbons adsorbed per unit of $\text{SiO}_2\text{-NP/AC}$ mass increased as initial chlorinated hydrocarbons concentration increased due to the increase of mass transfer between the solution and the adsorbent by action of the concentration factor which is considered as the driving force in the adsorption process. The amount adsorbed of chlorinated hydrocarbons per gram of $\text{SiO}_2\text{-NP/AC}$ after 10 min increased from 1.47 to 8.80 mg/g for dichloromethane, 3.40 to 15.99 mg/g for chloroform and from 4.58 to 18.61 mg/g for carbon tetrachloride as the initial chlorinated hydrocarbons concentration was increased from 5 to 20 mg/L. Therefore the adsorption was fast in the first 10 min and then decrease to be constant at the equilibrium point. The time of saturation is almost reached in 30 min.

Figure 6.6 Effect of contact time on adsorption of (a) dichloromethane, (b) chloroform, (c) carbon tetrachloride at different concentrations, and temperature 25°C.

6.3 Effect of adsorbent dosage

The amount of the adsorbent is an essential factor because it can identify the capacity of the adsorption at certain initial concentration of the adsorbate (Ouazene N 2010), fig (6.7) shows the effect of SiO₂-NP/AC dosage on the removal of chlorinated hydrocarbons. Different adsorbent dosages were applied for dichloromethane, chloroform and carbon tetrachloride at initial concentration 10 mg/L temperature, 25°C and shaking time 60 min. The results illustrated that when the adsorbent dosage increased, the percent removal of chlorinated hydrocarbons was increased from 39.96 % to 91.00 % for dichloromethane, from 77.03% to 97.18 % for chloroform and from 93.71% to 99.91 % for carbon tetrachloride, with an increase of adsorbent dosage from 0.25 to 5.00 g/L. This may be

attributed to the large surface area and vacant pore volume as a result of increase the adsorbent mass in addition to the high number of adsorption active sites and more functional groups for a constant concentration of chlorinated hydrocarbons (Y.H. Li 2003, A. R. V.K. Gupta 2008). However, when the adsorbent dose exceeded 3 g/L, the increase of percent removal of chlorinated hydrocarbons was insignificantly increased (Mittal A 2005, VK 2011). The removal percentage of chlorinated hydrocarbons in solution was calculated by Eq. (6.1) as follow:

$$\% \text{ Removal} = \frac{C_o - C_e}{C_o} \times 100 \quad (6.1)$$

Figure 6. 7 Effect of adsorbent dosage on the adsorption of dichloromethane, chloroform and carbon tetrachloride at different concentrations, and temperature 25°C.

6.4 Adsorption kinetics

The kinetic studies explain the rate control step and the equilibrium of the adsorption process. Also, the adsorption kinetic describes the interaction between adsorbent and solution interface and it can identify the mechanism of the adsorption processes, which might be described by the pseudo first-order (A. Sharma 2004), pseudo second-order rate equation (HoYS 2001) and intraparticle diffusion models (Wang S B 2008). The agreement between experimental results and the kinetic model expected values was indicated by the correlation coefficient (R^2) values. However, the relatively high (R^2) value it gives evidence for the successfully obeying a certain kinetic model of chlorinated hydrocarbons adsorption.

6.4.1 The pseudo-first order model

The pseudo-first order equation was used to interpret the adsorption data collected at three different initial concentrations of chlorinated hydrocarbons for investigating the controlling mechanism of the adsorption steps (A. Sari 2008). This model can be described by the following Lagergren rate equation (Lagergren 1898):

$$\log(q_e - q_t) = \frac{k_1}{2.303} t \quad (6.2)$$

Where k_1 is the Lagergren rate constant (1/min), q_e and q_t are the quantity of chlorinated hydrocarbons (mg/g) at contact time t and at equilibrium, respectively. The plots of $\log(q_e - q_t)$ versus t represented in fig (6.8), the values of the rate constant k_1 and adsorption quantity q_e at equilibrium were calculated from the slopes and intercepts table (6.1). The value of the correlation coefficient (R^2) of the plots was low for the three concentrations, which indicate the lack of linearity. The correspondence between the calculated q_e from

the equation (6.2) and observed q_e was very poor. This indicated that the adsorption of chlorinated hydrocarbons did not obey the pseudo-first-order kinetic model and the mechanism of the adsorption on the surface of the $\text{SiO}_2\text{-NP/AC}$ may not fit the pseudo-first-order model well.

Figure 6. 8 Lagergren first order plot for adsorption of (a) dichloromethane (b) chloroform (c) Carbon tetrachloride at different concentrations and temperature 25°C.

6.4.2 The pseudo-second order model

The pseudo second-order rate equation for the adsorption kinetic was explained by the following equation (HoYS 2000):

$$\frac{dq_t}{dt} = k_2(q_e - q_t)^2 \quad (6.3)$$

Where k_2 is the rate constant (g/mg.min), q_e and q_t are the adsorbed amount of the chlorinated hydrocarbons at equilibrium and time t , respectively. When the boundary conditions are applied from $t=0$ to $t=t$ and $q_t=0$ to $q_t=q_e$, the equation (6.4) after the integration becomes:

$$\frac{1}{q_e - q_t} = \frac{1}{q_e} + k_2 t \quad (6.4)$$

Equation (6.5) can be expressed in the linear form as below:

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (6.5)$$

Where h is the initial adsorption rate at $t = 0$, h (mg/g.min) can be described as :

$$h = k_2 q_e^2 \quad (6.6)$$

Therefore equation (6.6) can be written in a form as:

$$\frac{t}{q_t} = \frac{1}{h} + \frac{t}{q_e} \quad (6.7)$$

The plots of t/q_t against t of equation (6.7) at different initial concentrations (5,10 and 20 ppm) of the chlorinated hydrocarbons are shown in fig (6.9). The adsorption parameters were calculated and listed in table (6.1). From the plots, it was observed that the correlation coefficient values (R^2) ($R^2 > 0.99$) for all the data at different concentrations means high linearity and the adsorption kinetics between $\text{SiO}_2\text{-NP/AC}$ composite and the chlorinated hydrocarbons follow the pseudo-second order. Moreover, the agreement

between the q_e , cal and q_e , (Rodrigues LA 2010) prove the fitting is best represented by the pseudo-second order model. It can be suggested that the overall rate of chlorinated hydrocarbons adsorption appears to be controlled by a chemisorption mechanism through the participation of electrons or by covalent bonds between the surface of $\text{SiO}_2\text{-NP/AC}$ and adsorbate.

Figure 6. 9 Linear regression of kinetics Plot: pseudo second order for (a) dichloromethane (b) Chloroform (c) Carbon tetrachloride at different concentrations and temperature 25°C.

6.4.3 The intraparticle diffusion model

The investigation of the possibility of intraparticle diffusion and prediction of the rate determining step were carried out by using Weber and Morris model (W.J. Weber 1963, Wu 2007). The rate constants (k_{id}) can be determined by using the following equation:

$$q_t = k_{id}t^{1/2} + C \quad (6.8)$$

The plots of q_t versus $t^{1/2}$ are illustrated in fig (6.10). The lines of the different concentration does not go through the point of origin, which means the mechanism cannot determine the rate of the overall process, and the adsorption mechanism is likely to be very complex (G. Cunha 2010).

6.5 Adsorption isotherms

The adsorption isotherm describes the interactions between the adsorbate molecules in the liquid phase and the solid phase adsorbent (Hameed 2006). The maximum adsorption capacity can be determined from the isotherms. Various isotherm models were used for investigation of adsorption capacity in adsorption of chlorinated hydrocarbon from aqueous solution; three models were introduced in this study (Langmuir, Freundlich, and Temkin isotherms).

6.5.1 Langmuir isotherms model

The Langmuir explains that the monolayer adsorption process occurs between the adsorbate and homogeneous surface of the adsorbent which has a specific active sites and energies (Langmuir 1916, Deng H 2009). The linear equation is given by:

$$\frac{C_e}{q_e} = \frac{1}{k_L q_m} + \frac{C_e}{q_m} \quad (6.9)$$

Where k_L is Langmuir equilibrium constant (L/mg), and q_m (mg/g) is the quantity of the adsorbate in the adsorbent by monolayer adsorption. Both values were calculated from the plot C_e/q_e versus C_e fig (6.11). The characteristic parameter of Langmuir isotherm can be illustrated in terms of dimensionless equilibrium factor, R_L , also known as separation factor and is defined by Weber and Chakkravorti:

$$R_L = \frac{1}{1 + K_L C_o} \quad (6.10)$$

The plots of C_e/q_e versus C_e shows high linearity and is confirmed by the values of the correlation coefficient R^2 , which indicated that the isotherm data fit this model well. The Langmuir parameter constants were calculated and listed in table (6.2).

Figure 6. 11 Langmuir model for adsorption of (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations, and temperature 25°C.

6.5.2 Freundlich isotherms model

Freundlich model is usually used to express adsorption on a heterogeneous surface of an adsorbent (Freundlich 1906). The Freundlich is defined by the following logarithmic equation:

$$\ln q_e = \ln K_f + \frac{1}{n} \ln C_e \quad (6.11)$$

Where k_F (L/g) and n are the adsorption capacity and adsorption intensity, respectively, and can be obtained from the linear plot by plotting $\ln q_e$ versus $\ln C_e$ fig (6.12). The Freundlich isotherm constants, K_F and n , were calculated table (6.2). The n value is characteristic for the favorability of the adsorption process. The values of $n > 1$ demonstrate favorable adsorption conditions (Treybal 1968, V.J.P. Poots 1978, Y.S. Ho 1998). The correlation coefficient values indicate that the linearity is poor, but Freundlich

isotherm could be used to evaluate the chlorinated hydrocarbons adsorption capacity and adsorption intensity.

3

Figure 6. 12 Freundlich model for adsorption of (a) dichloromethane (b) Chloroform (c) Carbon tetrachloride at different concentrations, and temperature 25°C.

6.5.3 Temkin isotherm model

Temkin adsorption isotherm represents the amount of the energy needed for the adsorption by one layer on the surface of adsorbent. The linear form of Temkin model is given by:

$$\ln q_e = \frac{RT}{b_T} \ln K_T + \frac{RT}{b_T} \ln C_e \quad (6.12)$$

Where b_T is the temkin constant related to the heat of sorption (kJ/mol), k_T is the binding energy constant at equilibrium which is equal to the maximum binding energy (L/g), R is universal gas constant (8.314×10^{-3}), and T is the absolute temperature (degrees Kelvin) (M. Idrisa 2011). The plot of q_e versus $\ln(C_e)$ is illustrated in fig (6.13), and the isotherm data were calculated from the slope and intercept table (6.2).

Figure 6. 13 Temkin model for adsorption of (a) dichloromethane (b) Chloroform (c) Carbon tetrachloride at different concentrations, and temperature 25°C.

6.6 Regeneration of the adsorbent

Regarding to the applications, the disposal of adsorbent as by products in the adsorption process is not economically feasible or recommended, therefore regeneration should be attempted (H. M. K. Yogesh Kumar 2013). The possibility of regenerating the adsorbent with a chemical and thermal treatment was tested. The chemical treatment was examined using solvent and thermal treatment was conducting by heating the adsorbent/sorbent up to 100°C. The material was tested for three cycles and the results showed excellent regenerability with almost the same percentage of removal fig (6.14).

Figure 6. 14 regeneration adsorption of (a) dichloromethane (b) Chloroform (c) Carbon tetrachloride at SiO₂–NP/AC dosage 0.1 g/L, contact time 60 min, and temperature 25°C.

CHAPTER 7

Sorption by CeO₂-NP/AC

7.1 Characterization of CeO₂-NP/AC

The morphology of CeO₂-NP/AC composite is presented in fig (7.2). As shown, the surface of the composite has a large number of nanoparticles, which represents additional active sites for surface adsorption on the activated carbon surface. Using the scale of the SEM image, one may estimate the average diameter of the silica particles as approximately 60 nm. This value has been confirmed by taking the average of the nanoparticles on several images. The EDX spectrum presented in fig (7.3), indicates which elements are represented in the composite, i.e. carbon, oxygen and cerium. Thermal stability of CeO₂-NP/AC composite was also investigated. Thermal analysis of the prepared composites is very important to determine their thermal stability and optimal conditions of calcination. In fig (7.5) example of TGA curve collected for the sample in flowing nitrogen is presented. As it is shown, CeO₂-NP/AC has better thermal stability than pristine activated carbon. The FT-IR spectrum of CeO₂-NP/AC composite is illustrated in fig (7.1). The band laying around 1640 cm⁻¹ represents the enhancement in the aromatic C=C groups (carbonization). The strong and broad band at 3400 cm⁻¹ represent O-H mode, and the band at 2900 cm⁻¹ is C-H aliphatic mode. The band at 1054 cm⁻¹ can be attributed to C-O stretching vibration. The FTIR spectrum of the cerium oxide nanoparticles exhibits strong broad peak below 700 cm⁻¹, which is due to the (Ce-O)

vibration mode. The XRD patterns of CeO₂-NP/AC composite is illustrated in fig (7.4). At low diffraction angles, the typical broad diffraction band of ceria nanoparticles can be observed. The XRD pattern of the carbon exhibits a weak diffraction peak that is attributable to the aromatic carbon sheets oriented in a considerably random fashion.

7.2 Effect of contact time and initial concentration

The effect of contact time on the removal capacity of chlorinated hydrocarbons by using $\text{CeO}_2\text{-NP/AC}$ (derived from rubber tires waste) composite is illustrated in fig (7.6), and it shows that the removal of chlorinated hydrocarbons increased quickly with a contact time and then progressed by slower rate until it reach the saturation step. This result is due to the large number of active sites on the external surface of the adsorbent. Consequently the initial step of the adsorption was initially very fast but was then followed by internal diffusion process that is a slow step. Moreover, the large number of vacant active sites observed after a certain time indicate that it is difficult to uptake the solute molecules, due to the repulsion force between the solute molecules on the $\text{CeO}_2\text{-NP/AC}$ and bulk phases (Y. Wu 2008, M.K. Aroua 2008). However, the quantity of chlorinated hydrocarbons adsorbed per unit of $\text{CeO}_2\text{-NP/AC}$ mass increased as the initial concentration of

chlorinated hydrocarbons increased due to the increase of mass transfer between the solution and the adsorbent by action of the concentration factor, which is considered as the driving force in the adsorption process (Garg 2003, Selvi 2001) . The amount adsorbed of chlorinated hydrocarbons per gram of $\text{CeO}_2\text{-NP/AC}$ after 10 min increased from 1.47 to 8.80 mg/g for dichloromethane, 3.40 to 15.99 mg/g for chloroform and from 4.58 to 18.61 mg/g for carbon tetrachloride as the initial chlorinated hydrocarbons concentration was increased from 5 to 20 mg/L. Therefore the adsorption was very rapid in the first 10 min and then decrease to be constant at the equilibrium point. The time of saturation is almost reached in 30 min.

Figure 7. 6 Effect of contact time on adsorption of (a) dichloromethane, (b) chloroform, (c) carbon tetrachloride at different concentrations, and temperature 25°C.

7.3 Effect of adsorbent dosage

The amount of the adsorbent is a significant factor because it can identify the capacity of the adsorption for a given initial concentration of the adsorbate (Ouazene N 2010). fig

(7.7) shows the effect of CeO₂-NP/AC dosage on the removal of chlorinated hydrocarbons. Different adsorbent dosage were applied for dichloromethane, chloroform, and carbon tetrachloride at initial concentration 10 mg/L temperature, 25°C , and a shaking time 60 min. The results illustrated that when the adsorbent dosage increased, the percent removal of chlorinated hydrocarbons was increased from 32.04 % to 82.72 % for dichloromethane, from 57.14% to 99.40 % for chloroform and from 71.74% to 89.42 % for carbon tetrachloride, with an increase of adsorbent dosage from 0.25 to 5.00 g/L. This may be attributed to the large vacant active sites as a result of increase the adsorbent mass in addition to high number of adsorption active sites more functional groups for a constant concentration of chlorinated hydrocarbons (Y.H. Li 2003, A. R. V.K. Gupta 2008). However, when the adsorbent dose exceeded 3 g/L, the increase of percent removal of chlorinated hydrocarbons was insignificantly increased (Mittal A 2005, VK 2011). The removal percentage of chlorinated hydrocarbons in solution was calculated by Eq. (7.1) as follow:

$$\% \text{ Removal} = \frac{C_o - C_e}{C_o} \times 100 \quad (7.1)$$

Figure 7. 7 Effect of adsorbent dosage on the adsorption of dichloromethane, chloroform and carbon tetrachloride at different concentrations, and temperature 25°C.

7.4 Adsorption kinetics

The kinetic studies explain the rate control step and the equilibrium of the adsorption process. Also, the adsorption kinetic describes the interaction between adsorbent and solution interface and can determine the mechanism of the adsorption processes. Such a mechanism might be explained by the pseudo first-order (A. Sharma 2004), pseudo second-order rate equation (HoYS 2001) and intraparticle diffusion models (Wang S B 2008). The agreement between the adsorption experimental data and the kinetic model expected values could be explained by the correlation coefficient (R^2) values.

7.4.1 The pseudo-first order model

The pseudo-first order equation was used to examine the kinetic adsorption data collected at three different initial concentrations of chlorinated hydrocarbons for investigation the rate controlling mechanism of the adsorption process (A. Sari 2008). The pseudo-first order equation can be described by the following Lagergren model (Lagergren 1898):

$$\log(q_e - q_t) = \frac{k_1}{2.303} t \quad (7.2)$$

Where k_1 is the Lagergren rate constant (1/min), q_e and q_t are the quantities of chlorinated hydrocarbons (mg/g) at contact time t and at equilibrium, respectively. The plots of $\log(q_e - q_t)$ versus t represented in fig (7.8), the values of the rate constant k_1 and adsorption quantity q_e at equilibrium were calculated from the plots illustrated in table (7.2). The value of the correlation coefficient (R^2) of the plots was low for the three concentrations, which indicate the lack of linearity for pseudo-first-order kinetic model. The correspondence between the calculated q_e from the equation (7.2) and observed q_e was very poor. This indicated that the adsorption of chlorinated hydrocarbons did not obey the pseudo-first-order kinetic model, and the mechanism of the adsorption on the surface of the $\text{CeO}_2\text{-NP/AC}$ may not follow the pseudo-first-order model well.

Figure 7. 8 Lagergren first order plot for adsorption of (a) dichloromethane (b) chloroform (c) Carbon tetrachloride at different concentrations and temperature 25°C.

7.4.2 The pseudo-second order model

The pseudo second-order model of the adsorption kinetic was explained by the following equation (Ho YS 2000):

$$\frac{dq_t}{dt} = k_2(q_e - q_t)^2 \quad (7.3)$$

Where k_2 the rate constant (g/mg.min), q_e and q_t are the adsorbed amount of the chlorinated hydrocarbons at equilibrium and time t , respectively. When the boundary conditions are applied from $t=0$ to $t=t$ and $q_t=0$ to $q_t=q_e$, the equation (7.4) after the integration becomes:

$$\frac{1}{q_e - q_t} = \frac{1}{q_e} + k_2 t \quad (7.4)$$

Equation (7.5) represents the integrated form of pseudo-second-order model it can be expressed in the linear form as below:

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (7.5)$$

Where h is the initial adsorption rate at $t = 0$, h (mg/g.min) can be described as :

$$h = k_2 q_e^2 \quad (7.6)$$

Therefore equation (7.6) can be written in a form as:

$$\frac{t}{q_t} = \frac{1}{h} + \frac{t}{q_e} \quad (7.7)$$

The plots of t/q_t against t of equation (7.7) at different initial concentrations (5,10 and 20 ppm) of the chlorinated hydrocarbons are shown in fig (7.9). The adsorption parameter q_e , cal and k_2 were calculated from the plots and listed in table (7.2). From the plots it was observed that the correlation coefficient values (R^2) more than ($R^2 > 0.99$) from all the data at different concentrations, which means high linearity and the adsorption kinetics between SiO_2 -NP/AC composite and the chlorinated hydrocarbons follow the pseudo-second order. Moreover the correspondence between the q_e , cal and q_e , (Rodrigues LA 2010) illustrate the fitting of this model. It can be suggested that the rate of the adsorption seems to be controlled by a chemisorption mechanism through the participation of electrons or by covalent bonds between the surface of CeO_2 -NP/AC and adsorbate.

Figure 7. 9 Linear regression of kinetics Plot: pseudo second order for (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations and temperature 25°C.

7.4.3 The intraparticle diffusion model

The investigation for the possibility of intraparticle diffusion and prediction of the rate controlling step in the adsorption process were carried out by using Weber and Morris model (W.J. Weber 1963, Wu 2007). The rate constants of intra-particle diffusion (k_{id}) can be identified by using the following equation:

$$q_t = k_{id}t^{\frac{1}{2}} + C \quad (7.8)$$

Where q_t is the adsorbed quantity of chlorinated hydrocarbons at time t . The plots of q_t versus $t^{1/2}$ are illustrated in fig (7.10) The lines of the different concentration does not pas through the origin, which means the mechanism cannot determine the rate of the overall

adsorption process, and the adsorption mechanism suppose to be very complex (G. Cunha 2010).

Figure 7. 10 Intraparticle diffusion kinetic plot for (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations and temperature 25°C.

7.5 Adsorption isotherm

The adsorption isotherm describes the interactions between the molecules of the adsorbate in the liquid phase and the solid phase adsorbent (Hameed 2006). Also, the maximum adsorption capacity can be determined from the isotherms. Various isotherm models were used for investigation of adsorption capacity in adsorption of chlorinated hydrocarbon from aqueous solution. The three models introduced in this study are Langmuir, Freundlich, and Temkin isotherms.

Table 7. 2 Kinetic constant parameters obtained from chlorinated hydrocarbons adsorption on CeO₂–NP/AC.

7.5.1 Langmuir isotherm model

The Langmuir explains that the adsorption process occurs on homogeneous surface of the adsorbent by monolayer of the adsorbate, which has a specific active sites and energies (Langmuir 1916, Deng H 2009). The linear equation is given by:

$$\frac{C_e}{q_e} = \frac{1}{k_L q_m} + \frac{C_e}{q_m} \quad (7.9)$$

Where k_L is Langmuir equilibrium constant (L/mg), and q_m (mg/g) is the maximum amount by monolayer adsorption, they were calculated from a plot C_e/q_e versus C_e fig (7.11). The characteristic dimensionless equilibrium parameter for this model is the separation factor, defined by Weber and Chakkravorti:

$$R_L = \frac{1}{1 + K_L C_o} \quad (7.10)$$

The plots of C_e/q_e versus C_e shows high linearity confirmed by the values of the correlation coefficient R^2 , which indicated that the isotherm data fit the this model well. The Langmuir parameters constants were calculated and listed in table (7.3).

Figure 7. 11 Langmuir model for adsorption of (a) dichloromethane (b) chloroform (c) carbon tetrachloride at different concentrations, and temperature 25°C.

7.5.2 Freundlich isotherm model

Freundlich model is usually used to explain the adsorption by a heterogeneous surface of an adsorbent (Freundlich 1906). The well-known form of Freundlich equation is defined as following:

$$\ln q_e = \ln K_f + \frac{1}{n} \ln C_e \quad (7.11)$$

Where k_F (L/g) and n are the adsorption capacity and adsorption intensity, respectively.

The Freundlich constants can be obtained by plotting $\ln q_e$ versus $\ln C_e$ fig (7.12). The Freundlich isotherm constants, K_F and n , were calculated table(7. 2). The values of $n > 1$ represent favorable adsorption condition (Treybal 1968, V.J.P. Poots 1978, Y.S. Ho 1998). The values of the correlation coefficient gives an indication for the poor linearity,

but Freundlich isotherm could be used to investigate the chlorinated hydrocarbons adsorption capacity and adsorption intensity.

Figure 7. 12 Freundlich model for adsorption of (a) dichloromethane (b) Chloroform (c) Carbon tetrachloride at different concentrations, and temperature 25°C.

7.5.3 Temkin isotherm model

The Temkin isotherm represents the quantity of heat needed for the adsorption by one layer of adsorbate on the surface of adsorbent. The linear form of Temkin model is given by:

$$\ln q_e = \frac{RT}{b_T} \ln K_T + \frac{RT}{b_T} \ln C_e \quad (7.12)$$

Where b_T is the temkin constant related to the heat of sorption (kJ/mol), K_T is the equilibrium binding constant and is equal to the maximum binding energy (L/g), R is universal gas constant (8.314×10^{-3}), and T is the absolute temperature (degrees Kelvin)

(M. Idrisa 2011). The plot of q_e versus $\ln(C_e)$ is illustrated in fig (7.13) and the isotherm constants were determined from the slope and intercept table (7.3).

Figure 7. 13 Temkin model for adsorption of (a) dichloromethane (b) Chloroform (c) Carbon tetrachloride at different concentrations, and temperature 25°C.

Table 7. 3 Langmuir, Freundlich, and Temkin isotherm constants for chlorinated hydrocarbon adsorption on CeO₂–NP/AC.

7.6 Regeneration of adsorbent

Regarding to the applications, the disposal of adsorbent as byproducts in the adsorption process is not economical; therefore, regeneration should be carried out (H. M. K. Yogesh Kumar 2013). The possibility of regenerating the adsorbent with a chemical and thermal treatment was tested. The chemical treatment was examined using solvent, and thermal treatment was conducting by heating the adsorbent/sorbent up to 100°C. The material was tested for three cycles, and the results showed excellent re-generality with almost the same percentage of removal fig (7.14).

Figure 7. 14 regenatration adsorption of (a) dichloromethane (b) Chloroform (c) Carbon tetrachloride at $\text{SiO}_2\text{-NP/AC}$ dosage 0.1 g/L, contact time 60 min, and temperature 25°C.

Conclusion

In this work, four adsorbents were synthesized: activated carbon derived from the rubber waste tires, ZnO-NP/AC, SiO₂-NP/AC and CeO₂-NP/AC composites. These materials were characterized by the means of SEM, EDX, FTIR, XRD, TGA. The prepared materials were tested for the adsorptive removal of dichloromethane, trichloromethane and carbon tetrachloride from aqueous media at ambient conditions, in batch adsorption mode. Waste rubber tires are cost-effective and are a readily available precursor material that can act as a better replacement source for commercial AC. The results indicate that the activated carbon loaded with nanoparticles exhibited better sorption activity than the pristine activated carbon. Also, the presence of the metal oxide nanoparticles enhances the thermal stability of the composites materials. The order of the sorption efficiency is as following: SiO₂-NP/AC > ZnO-NP/AC > CeO₂-NP/AC > AC. The experimental data were found to better obey the pseudo-second-order kinetic model, and the isotherms could be well described by the Langmiur isotherm equation for SiO₂-NP/AC and ZnO-NP/AC, but the AC and CeO₂-NP/AC were found to follow the Freundlich isotherm equation. All the materials were reused for several times after being thermally regenerated, and the obtained removal capacities were approximately the same for three cycles.

Vitae |

Name : MOHAMMED SALAH AHMED ABDELBASSIT

Nationality : Sudanese

Date of Birth : 05/04/1988

Email : mohammed.bassit@live.com

Address : Khartoum, Sudan

Academic Background : B.Sc. in Chemistry from Sudan University of Science and Technology

Career history:

January 2012-May 2014 : Research assistant at KFUPM, Saudi Arabia

May 2011 - January 2012 : Quality control chemist in Emarati Foodstuff & plastic packing company in (Sudan)

October 2009 - February 2011 : Teaching assistant in the chemistry department at Sudan University of Science and Technology

Training and Applied Courses :

- ✓ Quality Control of water processing and soft drinks in Nile soft drinking factory, duration (05.12.2009-20.12.2009) and Dal Foodstuffs Company from (01.03.2010- 30.03.2010).
- ✓ Ministry of science and technology central labs (Sudan) in the analytical chemistry department mastering different techniques, with adequate specificity with atomic absorption spectroscopy "AAS" Gas Chromatography –Mass Spectrometry "GC-MS"

High Performance Liquid Chromatography “HPLC” & “UV-VIS” Spectroscopy From
25.4.2010 up to 04.05.2010.

- ✓ The Research Institute (R.I) at the King Fahad University of Petroleum and Minerals as a part-time research assistant in water and environment center, my job was on soil and water samples pretreatment and analysis of trace metals by ICP-MS & ICP-OES instruments from (01.02.2013-31.07.2013).
